

This guide walks you through installing the Archipelago mod for **A Dance of Fire and Ice** and writing the YAML file that configures your run. No prior Archipelago experience is assumed.

## 1 · What you need

- **A Dance of Fire and Ice**, the Steam version.
- **Archipelago** 0.6.3 or newer. This is the launcher that generates and hosts multiworlds ([archipelago.gg](https://archipelago.gg)).
- **The ADOFAI mod client**. Download ADOFAI\_AP-Mod.zip from the mod's GitHub Releases page. The ZIP already bundles BepInEx, so there is nothing else to install.
- A stable internet connection (even a local game runs through a server).

## 2 · Install the mod

The mod runs through BepInEx, which is included in the ZIP. You only need to drop its contents next to the game executable.

1. In Steam, right-click **A Dance of Fire and Ice** → **Manage** → **Browse local files**. This opens the game folder (the one containing A Dance of Fire and Ice.exe).
2. Download ADOFAI\_AP-Mod.zip from the mod's Releases page and extract it.
3. Copy the **contents** of the archive into the game folder, so that BepInEx\, winhttp.dll and doorstop\_config.ini sit **next to** the game's .exe (not inside a sub-folder).
4. Launch the game once, then close it. BepInEx creates its folders on first run.
5. Confirm the mod is installed: the file BepInEx\plugins\ADOFAI\_AP.dll exists.

**Verify it loaded** Launch the game and press M. The Archipelago connection window should appear. If it does not, open BepInEx\LogOutput.log and look for lines starting with [com.shotai.ADOFAI\_AP].

## 3 · Connect in-game

Press **M** at any time to open or close the mod menu. The game pauses while the menu is open.

- **Username:** this must match the name in your YAML (your slot).
- **Server IP** and **Port:** shown on the room page by whoever hosts the game.
- **Password:** only if the room has one; otherwise leave it empty.
- After connecting: **Level selection** shows the levels you have unlocked (green = available, gold = goal, grey = already done); **Options** holds DeathLink settings.

## 4 · The YAML, in plain terms

A **YAML** is a small text file that describes *your* slot: your name, which worlds are in play, and how you win. Archipelago reads every player's YAML to build one shared randomized game. One file per player.

- Indentation matters: the game's settings are nested under the line `A Dance of Fire and Ice:` and indented by two spaces.
- Save the file as `YourName.yaml` and place it in `Archipelago\Players\`.
- Toggles are `true` / `false`. Everything defaults to `false`, so you only turn on what you want.

**Easiest path: the configurator** Instead of writing this by hand, use the interactive **ADOFAI YAML Configurator**: tick the worlds and goal you want and it builds the file for you. Ask the author for the link.

### Minimal working example

```
# A Dance of Fire and Ice - Archipelago slot
name: ShotAl
game: A Dance of Fire and Ice
A Dance of Fire and Ice:
  completion_goal: allX
  percentage_goal_completion: 80
  goal_levels: ""
  main_worlds_tuto: false
  death_link: false
```

This runs the base worlds (1-12), wins when every boss level is cleared plus 80% of the rest, and keeps everything else off.

## 5 · Worlds you can add

Each world adds its boss level (named -X). The matching ... **tuto** toggle adds that world's shorter practice stages as extra locations, so more checks and a longer run. Main worlds (1-12) are always included.

| World toggle                       | Tutorial toggle                         | Adds                                            |
|------------------------------------|-----------------------------------------|-------------------------------------------------|
| (always on)                        | <code>main_worlds_tuto</code>           | Tutorials of worlds 1-12                        |
| <code>xtra_worlds</code>           | <code>xtra_worlds_tuto</code>           | Xtra worlds: XS, PA, XH, XC, XF, XR, RJ, XN, XM |
| <code>crown_worlds</code>          | <code>crown_worlds_tuto</code>          | Crown worlds: XO, XT, XI                        |
| <code>star_worlds</code>           | <code>star_worlds_tuto</code>           | Star worlds: MN, ML, MO                         |
| <code>neon_cosmos_worlds</code>    | <code>neon_cosmos_worlds_tuto</code>    | Neon Cosmos worlds: T1-T5                       |
| <code>neon_cosmos_worlds_ex</code> | <code>neon_cosmos_worlds_ex_tuto</code> | Neon Cosmos EX: T1EX-T4EX                       |
| <code>b_world</code>               | <code>b_world_tuto</code>               | The B world                                     |
| <code>ar_world</code>              | <code>ar_world_tuto</code>              | The AR world                                    |
| <code>april_fools_worlds</code>    | (none)                                  | April Fools worlds: 1J-6J, BJ                   |

## 6 · Victory & goal options

| Option                     | Values / range    | Default | What it does                                                                               |
|----------------------------|-------------------|---------|--------------------------------------------------------------------------------------------|
| completion_goal            | allX   goalLevels | allX    | How goals are chosen. allX = every -X boss is a goal. goalLevels = you pick them yourself. |
| percentage_goal_completion | 0 - 100           | 80      | Share of the non-goal levels you must also complete to win.                                |
| goal_levels                | level codes       | (empty) | Only used when completion_goal = goalLevels. Space-separated, e.g. "7-X 8-X XS-X".         |
| death_link                 | true   false      | false   | When you die, every DeathLink player dies too, and vice-versa.                             |

### How the two goal modes feel

- **allX**: the whole campaign. You must beat the final boss (-X) of every enabled world, and clear the percentage of everything else. Good default.
- **goalLevels**: a focused run. You list exactly which levels count as goals; the percentage still applies to the rest. Pick only levels from worlds you enabled; disabled ones are ignored.

### Recipes

```
# Short & focused: just finish worlds 7 and 8
completion_goal: goalLevels
goal_levels: "7-X 8-X"
percentage_goal_completion: 50
```

```
# Full completionist: every boss + all tutorials
completion_goal: allX
percentage_goal_completion: 100
main_worlds_tuto: true
xtra_worlds: true
xtra_worlds_tuto: true
```

## 7 · Generate and play

### Local game (just you):

1. Put your .yaml in Archipelago\Players\.
2. Open the Archipelago Launcher → **Generate**.
3. Click **Host** and choose the new archive created in Archipelago\output\.
4. Launch ADOFAI, press **M**, and connect using the address, port and your slot name.

### Join someone else's multiworld:

1. Send your .yaml to the host so they can include your slot.
2. Once the room is up, launch ADOFAI, press **M**, and connect with the room's address and port and your slot name.

## 8 • Troubleshooting

| Symptom                     | Fix                                                                                                           |
|-----------------------------|---------------------------------------------------------------------------------------------------------------|
| Pressing M does nothing     | The mod did not load. Check BepInEx\plugins\ADOF_AI_AP.dll exists, and read BepInEx\LogOutput.log for errors. |
| "Failed to connect"         | Re-check the address, port and that your slot name matches the YAML exactly (case-sensitive).                 |
| A level stays locked        | You have not received its key item yet. Play the levels you can; keys arrive as you and others send checks.   |
| A goal level never appears  | It belongs to a world you did not enable, or was filtered out of goal_levels. Enable that world in the YAML.  |
| Generation fails on my YAML | Check indentation (2 spaces) and that option names are spelled exactly as in the tables above.                |
